The mathtools package*

Morten Høgholm, Lars Madsen

2019/07/31

Abstract
The mathtools package is an extension package to amsmath. There are two things on mathtools’ agenda: (1) correct various bugs/deficiencies in amsmath until these are fixed by the AMS and (2) provide useful tools for mathematical typesetting, be it a small macro for typesetting a prescript or an underbracket, or entirely new display math constructs such as a multlined environment.

*This file has version number v1.22, last revised 2019/07/31.
1 Introduction

Although amsmath provides many handy tools for mathematical typesetting, it is nonetheless a static package. This is not a bad thing, because what it does, it mostly does quite well and having a stable math typesetting package is "a good thing." However, amsmath does not fulfill all the needs of the mathematical part of the \LaTeX\ community, resulting in many authors writing small snippets of code for tweaking the mathematical layout. Some of these snippets have also been posted to newsgroups and mailing lists over the years, although more often than not without being released as stand-alone packages.

The \texttt{mathtools} package is exactly what its name implies: tools for mathematical typesetting. It is a collection of many of these often needed small tweaks—with some big tweaks added as well. It can only do so by having harvesting newsgroups for code and/or you writing the maintainers with wishes for code to be included, so if you have any good macros or just macros that help you when writing mathematics, then don’t hesitate to report them. It is easiest to just contact Lars Madsen at
daleif@math.au.dk

This is of course also the address to use in case of bug reports. Please put ‘\texttt{mathtools}’ in the subject line.

Update 2013: We now make \texttt{\(\langle\langle\)} and \texttt{\(\[\[\)} robust (can be disabled via \texttt{nonrobust} package option).
2 Package loading

The mathtools package requires amsmath but is able to pass options to it as well. Thus a line like
\usepackage[fleqn,tbtags]{mathtools}
is equivalent to
\usepackage[fleqn,tbtags]{amsmath}
\usepackage{mathtools}

2.1 Special mathtools options

\begin{itemize}
  \item fixamsmath
  \item donotfixamsmathbugs
\end{itemize}

The option \texttt{fixamsmath} (default) fixes two bugs in amsmath.\footnote{See the online \LaTeX{} bugs database \url{http://www.latex-project.org/cgi-bin/ltxbugs2html} under \LaTeX{} problem reports 3591 and 3614.} Should you for some reason not want to fix these bugs then just add the option \texttt{donotfixamsmathbugs} (if you can do it without typos). The reason for this extremely long name is that I really don't see why you wouldn't want these bugs to be fixed, so I've made it slightly difficult not to fix them.

\begin{itemize}
  \item allowspaces
  \item disallowspaces
\end{itemize}

Sometimes amsmath gives you nasty surprises, as here where things look seemingly innocent:
\[
\begin{gathered}
[p] = 100 \\
[v] = 200
\end{gathered}
\]

Without mathtools this will result in this output:
\[
[p] = 100
\]
\[
[v] = 200
\]

Yes, the \texttt{[p]} has been gobbled without any warning whatsoever.\footnote{amsmath thought \texttt{[p]} was an optional argument, checked if it was \texttt{t} or \texttt{b} and when both tests failed, assumed it was a \texttt{c}.} This is hardly what you'd expect as an end user, as the desired output was probably something like this instead:
\[
[p] = 100
\]
\[
[v] = 200
\]
With the option disallowspaces (default) mathtools disallows spaces in front of optional arguments where it could possibly cause problems just as amsmath does with \ inside the display environments. This includes the environments gathered (and also those shown in § 4.5 on page 35), aligned, multlined, and the extended matrix-environments (§ 3.4.1 on page 16). If you however want to preserve the more dangerous standard optional spaces, simply choose the option allowspaces.

3 Tools for mathematical typesetting

\mathtoolsset{(key val list)}

Many of the tools shown in this manual can be turned on and off by setting a switch to either true or false. In all cases it is done with the command \mathtoolsset. A typical use could be something like

\mathtoolsset{
  showonlyrefs,
  mathic % or mathic = true
}

More information on the keys later on.

3.1 Fine-tuning mathematical layout

Sometimes you need to tweak the layout of formulas a little to get the best result and this part of the manual describes the various macros mathtools provides for this.

3.1.1 A complement to \smash, \llap, and \rlap

\mathllap{{\mathstyle}\{\math}\}} \mathclap{{\mathstyle}\{\math\}} \mathrlap{{\mathstyle}\{\math\}}

\mathmbox{{\math}\}} \mathmakebox[\width]{\pos}{\math}

In [1], Alexander R. Perlis describes some simple yet useful macros for use in math displays. For example the display

\[
X = \sum_{1 \le i \le j \le n} X_{ij}
\]

contains a lot of excessive white space. The idea that comes to mind is to fake the width of the subscript. The command \mathclap puts its argument in a zero width box and centers it, so it could possibly be of use here.

\[\]
\[ X = \sum_{\mathclap{1\le i\le j\le n}} X_{ij} \]
\]
\[ X = \sum_{1\le i\le j\le n} X_{ij} \]

For an in-depth discussion of these macros I find it better to read the article; an online version can be found at

Note that the definitions shown in the article do not exactly match the definitions in mathtools. Besides providing an optional argument for specifying the desired math style, these versions also work around a most unfortunate \LaTeX{} “feature.”\textsuperscript{3} The \texttt{\smash} macro is fixed too.

### 3.1.2 Forcing a cramped style

\texttt{\cramped[\mathstyle]{\textstyle}}

Let’s look at another example where we have used \texttt{\mathclap}:

\begin{equation}
\sum_{\mathclap{a^2<b^2<c}} \sum_{a^2<b^2<c}
\end{equation}

\(1\)

Do you see the difference? Maybe if I zoomed in a bit:

\[ \sum_{a^2<b^2<c} \sum_{a^2<b^2<c} \]

Notice how the limit of the right summation sign is typeset in a more compact style than the left. It is because \LaTeX{} sets the limits of operators in a \texttt{cramped} style. For each of \LaTeX{} four math styles (\texttt{\displaystyle}, \texttt{\textstyle}, \texttt{\scriptstyle}, and \texttt{\scriptscriptstyle}), there also exists a cramped style that doesn’t raise exponents as much. Besides in the limits of operators, \LaTeX{} also automatically uses these cramped styles in radicals such as \texttt{\sqrt} and in the denominators of fractions, but unfortunately there are no primitive commands that allows you to detect crampedness or switch to it.

\texttt{mathtools} offers the command \texttt{\cramped} which forces a cramped style in normal un-cramped math. Additionally you can choose which of the four styles you want it in as well by specifying it as the optional argument:

\textsuperscript{3}The faulty reboxing procedure.
You may be surprised how often the cramped style can be beneficial to your output. Take a look at this example:

\begin{quote}
The 2005 Euro\TeX{} conference is held in Abbaye des Prémontrés, France, marking the 16th ($2^{2^2}$) anniversary of both Dante and GUTenberg (the German and French \TeX{} users group resp.).
\end{quote}

The commands \texttt{\crampedllap}, \texttt{\crampedclap}, and \texttt{\crampedrlap} are identical to the three \texttt{\mathXlap} commands described earlier except the argument is typeset in cramped style. You need this in order to typeset (1) correctly while still faking the width of the limit.

\begin{equation*}
\sum_{\crampedclap{a^2<b^2<c}} \tag{\ref{eq:mathclap}^*}
\end{equation*}
Of course you could just type
\[ \sum_{\mathclap{\cramped{a^2<b^2<c}}} \]
but it has one major disadvantage: In order for \texttt{\mathclap} and \texttt{\cramped} to get the right size, \LaTeX{} has to process them four times, meaning that nesting them as shown above will cause \LaTeX{} to typeset $4^2$ instances before choosing the right one. In this situation however, we will of course need the same style for both commands so it makes sense to combine the commands in one, thus letting \LaTeX{} make the choice only once rather than twice.

\texttt{\begin{crampedsubarray}{\langle col\rangle \langle contents \rangle \end{crampedsubarray}}
\texttt{\crampedsubstack{\langle lines separated by \backslash \rangle}}\]
\texttt{\begin{crampedsubarray}{\langle col\rangle \langle contents \rangle \end{crampedsubarray}}
\texttt{\crampedsubstack{\langle lines separated by \backslash\rangle}}\]

If we go back to (1) and apply \texttt{\substack}, you’ll notice that the cramped style, the sum would normally apply, is now gone:
\[
\begin{align*}
\sum_{\substack{a^2<b^2<c}} & \quad \sum_{a^2<b^2<c} \\
\sum_{\substack{a^2<b^2<c}} & \quad \sum_{a^2<b^2<c}
\end{align*}
\]

We therefore provide a cramped version of \texttt{\substack}.

\[
\begin{align*}
\sum_{\crampedsubstack{a^2<b^2<c}} & \quad \sum_{a^2<b^2<c} \\
\sum_{\crampedsubstack{a^2<b^2<c}} & \quad \sum_{a^2<b^2<c}
\end{align*}
\]

Note: We may need to add a similar hook into multlined.

### 3.1.3 Smashing an operator

\texttt{\smashoperator{\langle pos\rangle \langle operator with limits \rangle}}

Above we showed how to get \LaTeX{} to ignore the width of the subscript of an operator.

---

\texttt{\begin{crampedsubarray}{\langle col\rangle \langle contents \rangle \end{crampedsubarray}}
\texttt{\crampedsubstack{\langle lines separated by \backslash\rangle}}\]
However this approach takes a lot of extra typing, especially if you have a wide superscript, meaning you have to put in \texttt{\crampedclap} in both sub- and superscript. To make things easier, mathtools provides a \texttt{\smashoperator} command, which simply ignores the width of the sub- and superscript. It also takes an optional argument, \texttt{l}, \texttt{r}, or \texttt{lr} (default), denoting which side of the operator should be ignored (smashed).

\[
V = \sum_{1 \leq i \leq j \leq n} V_{ij} \quad X = \smashoperator{\sum_{1 \leq i \leq j \leq n}^{3456}} X_{ij} \quad Y = \smashoperator[r]{\sum_{1 \leq i \leq j \leq n}} Y_{ij} \quad Z = \smashoperator[l]{\mathop{T}_{1 \leq i \leq j \leq n}} Z_{ij}
\]

Note that \texttt{\smashoperator} always sets its argument in display style and with limits even if you have used the \texttt{nosumlimits} option of amsmath. If you wish, you can use shorthands for \_ and ^ such as \texttt{\sb} and \texttt{\sp}.

3.1.4 Adjusting limits of operators

| \texttt{\adjustlimits{\{operator1\}}_{\{limit1\}} \{operator2\}_{\{limit2\}}} |

When typesetting two consecutive operators with limits one often wishes the limits of the operators were better aligned. Look closely at these examples:

\[
V = \sum_{1 \leq i \leq j \leq n} V_{ij} \quad X = \sum_{1 \leq i \leq j \leq n} X_{ij} \quad Y = \sum_{1 \leq i \leq j \leq n} Y_{ij} \quad Z = \mathop{T}_{1 \leq i \leq j \leq n} Z_{ij}
\]

a) \lim \max_{n \to \infty} \quad b) \lim \max_{p \geq n} \quad c) \lim \sup_{p \geq n} \quad d) \limsup \max_{n \to \infty}

a) looks okay, but b) is not quite as good because the second limit \((p^2 \geq n)\) is significantly taller than the first \((n \to \infty)\). With c) things begin to look really bad, because the second operator has a descender while the first doesn’t, and finally we have d) which looks just as bad as c). The command \texttt{\adjustlimits} is useful in these cases, as you can just put it in front of these consecutive operators and it’ll make the limits line up.

\[
V = \adjustlimits \sum_{1 \leq i \leq j \leq n} V_{ij} \quad X = \adjustlimits \sum_{1 \leq i \leq j \leq n} X_{ij} \quad Y = \adjustlimits \sum_{1 \leq i \leq j \leq n} Y_{ij} \quad Z = \mathop{T}_{1 \leq i \leq j \leq n} Z_{ij}
\]

a) \lim \max_{n \to \infty} \quad b) \lim \max_{p \geq n} \quad c) \lim \sup_{p \geq n} \quad d) \limsup \max_{n \to \infty} \quad p \geq n
The use of \ab instead of _ is allowed.

3.1.5 Swapping space above $\text{AMS}$ display math environments

One feature that the plain old equation environment has that the $\text{AMS}$ environments does not (because of thechnical reasons), is the feature of using less space above the equation if the situation presents itself. The $\text{AMS}$ environments cannot do this, but one can manually, using

\SwapAboveDisplaySkip

as the very first content within an $\text{AMS}$ display math environment. It will then issue an \abovedisplayskipshortskip instead of the normal \abovedisplayskip.

Note it will not work with the equation or multline environments.

Here is an example of the effect

\noindent\rule\textwidth{1pt}
\begin{align*} A &= B \end{align*}
\noindent\rule\textwidth{1pt}
\begin{align*} \SwapAboveDisplaySkip A &= B \end{align*}

\begin{align*} A &= B \end{align*}

A \neq B

3.2 Controlling tags

In this section various tools for altering the appearance of tags are shown. All of the tools here can be used at any point in the document but they should probably be affect the whole document, so the preamble is the best place to issue them.

3.2.1 The appearance of tags

Altering the layout of equation numbers in amsmath is not very user friendly (it involves a macro with three \@'s in its name), so mathtools provides an interface somewhat reminiscent of the page style concept. This way you can define several different tag forms and then choose the one you prefer.
As an example let’s try to define a tag form which puts the equation number in square brackets. First we define a brand new tag form:
\newtagform{brackets}{[]}{[]}
Then we activate it:
\usetagform{brackets}
The result is then
\[ E \neq mc^3 \] [2]
Similarly you could define a second version of the brackets that prints the equation number in bold face instead
\newtagform{brackets2}{\textbf[}{\textbf]}{\textbf]}
\usetagform{brackets2}
\begin{equation}
E \neq mc^3
\end{equation}
\[ E \neq mc^3 \] [3]
When you reference an equation with \eqref, the tag form in effect at the time of referencing controls the formatting, so be careful if you use different tag forms throughout your document.
If you want to renew a tag form, then use the command \renewtagform. Should you want to return to the standard setting then choose
\usetagform{default}
\textbf{Caveat regarding ntheorem:} If you like to change the appearence of the tags and you are also using the ntheorem package, then please postpone the change of appearance until after loading ntheorem. (In order to do its thing, ntheorem has to mess with the tags…)

\subsection{3.2.2 Showing only referenced tags}

\begin{quote}
\renewcommand*{\rmdefault}{ppl}\normalfont\itshape
10
\end{quote}
An equation where the tag is produced with a manual \tag* shouldn’t be referenced with the normal \eqref because that would format it according to the current tag format. Using just \ref on the other hand may not be a good solution either as the argument of \tag* is always set in upright shape in the equation and you may be referencing it in italic text. In the example below, the command \refeq is used to avoid what could possibly lead to confusion in cases where the tag font has very different form in upright and italic shape (here we switch to Palatino in the example):
\begin{quote}
\begin{equation}
\begin{quote}\renewcommand*{\rmdefault}{ppl}\normalfont\itshape
\end{quote}
\end{equation}
\end{quote}
\begin{equation*}
a = b \tag*{Q&A}
\end{equation*}

See Q&A or is it better with \ref{eq:example}?

Another problem sometimes faced is the need for showing the equation numbers for only those equations actually referenced. In mathtools this can be done by setting the key showonlyrefs to either true or false by using \mathtoolsset. You can also choose whether or not to show the manual tags specified with \tag or \tag* by setting the option showmanualtags to true or false.\footnote{I recommend setting showmanualtags to true, else the whole idea of using \tag doesn't really make sense, does it?} For both keys just typing the name of it chooses true as shown in the following example.

\mathtoolsset{showonlyrefs,showmanualtags}
\usetagform{brackets}
\begin{gather}
a = a \label{eq:a} \\ b = b \label{eq:b} \tag{**}
\end{gather}

This should refer to the equation containing $a = a$: \eqref{eq:a}. Then a switch of tag forms.
\mathtoolsset{showonlyrefs=false}
\usetagform{default}
\begin{align}
c &= c \label{eq:c} \\ d &= d \label{eq:d}
\end{align}

This should refer to the equation containing $d = d$: \eqref{eq:d}. Then a switch of tag forms.
\mathtoolsset{showonlyrefs=false}
\begin{equation}
e = e
\end{equation}

Back to normal. This should refer to the equation containing $a = a$: \eqref{eq:a}. Then a switch of tag forms.
\mathtoolsset{showonlyrefs=false}
\begin{equation}
a = a \tag{4}
\end{equation}
\begin{equation}
b = b \tag{**} \tag{5}
\end{equation}
This should refer to the equation containing $d = d$ \eqref{5}.

\[ e = e \]

Back to normal.

\[ f = f \] \eqref{6}

Note that this feature only works if you use \eqref or \refeq to reference your equations.

When using showonlyrefs it might be useful to be able to actually add a few equation numbers without directly referring to them.

\[ \\text{The syntax is somewhat similar to } \\text{\nocite. If a label in the list is undefined we will throw a warning in the same manner as } \ref. \]

**BUG 1:** Unfortunately the use of the showonlyref introduce a bug within amsmath's typesetting of formula versus equation number. This bug manifest itself by allowing formulas to be typeset close to or over the equation number. Currently no general fix is known, other than making sure that one's formulas are not long enough to touch the equation number.

To make a long story short, amsmath typesets its math environments twice, one time for measuring and one time for the actual typesetting. In the measuring part, the width of the equation number is recorded such that the formula or the equation number can be moved (if necessary) in the typesetting part. When showonlyref is enabled, the width of the equation number depend on whether or not this number is referred to. To determine this, we need to know the current label. But the current label is not known in the measuring phase. Thus the measured width is always zero (because no label equals not referred to) and therefore the typesetting phase does not take the equation number into account.

**BUG 2:** There is a bug between showonlyrefs and the ntheorem package, when the ntheorem option thmmarks is active. The shown equation numbers may come out wrong (seems to be multiplied by 2). Or the end marker may be placed in the wrong place if a proof ends with a displayed formula, and that formula is not refered to.

There are two possible solutions to this both involving empheq. The easiest fix is to add the following line

\[ \usepackage[overload,ntheorem]{empheq} \]

before loading ntheorem. But the overload option of course disables things like \intertext and \shortintertext.

The other thing to try is to use drop the overload option and use empheq on the very last expression, as in

\[ \begin{empheq}{align} 
A &= B \label{eq:32} \\& \\
\& = 1. \label{eq:31} 
\end{empheq} \]
The \texttt{empheq} package fixes some problems with \texttt{ntheorem} and lets \texttt{mathtools} get correct access to the equation numbers again.

### 3.3 Extensible symbols

The number of horizontally extensible symbols in standard \LaTeX{} and \texttt{amsmath} is somewhat low. This part of the manual describes what \texttt{mathtools} does to help this situation.

#### 3.3.1 Arrow-like symbols

\begin{alltt}
\begin{tabular}{ll}
\texttt{\leftarrow[\text{sub}]{\text{sup}}} & \texttt{\rightarrow[\text{sub}]{\text{sup}}} \\
\texttt{\Leftarrow[\text{sub}]{\text{sup}}} & \texttt{\Rightarrow[\text{sub}]{\text{sup}}} \\
\texttt{\hookleftarrow[\text{sub}]{\text{sup}}} & \texttt{\hookrightarrow[\text{sub}]{\text{sup}}} \\
\texttt{\mapsto[\text{sub}]{\text{sup}}} & \\
\end{tabular}
\end{alltt}

Extensible arrows are part of \texttt{amsmath} in the form of the commands

\begin{alltt}
\begin{tabular}{ll}
\texttt{\xrightarrow{\text{script}}} & \texttt{\xleftarrow{\text{script}}} \\
\end{tabular}
\end{alltt}

But what about extensible versions of say, \texttt{\leftarrow} or \texttt{\Longleftarrow}? It turns out that the above mentioned extensible arrows are the only two of their kind defined by \texttt{amsmath}, but luckily \texttt{mathtools} helps with that. The extensible arrow-like symbols in \texttt{mathtools} follow the same naming scheme as the one’s in \texttt{amsmath} so to get an extensible \texttt{\Leftarrow} you simply do a

\begin{alltt}
\begin{tabular}{l}
\texttt{\begin{array}{c}
A \ \texttt{\xleftarrow[\text{under}]{\text{over}}} B
\end{array}}
\end{tabular}
\end{alltt}

\begin{alltt}
\begin{tabular}{ll}
\texttt{\xrightleftharpoons[\text{sub}]{\text{sup}}} & \texttt{\xleftrightharpoons[\text{sub}]{\text{sup}}} \\
\texttt{\xleftrightarrow[\text{sub}]{\text{sup}}} & \texttt{\xleftharpoonup[\text{sub}]{\text{sup}}} \\
\texttt{\xleftharpoondown[\text{sub}]{\text{sup}}} & \texttt{\xleffrightharpoons[\text{sub}]{\text{sup}}} \\
\end{tabular}
\end{alltt}

\texttt{mathtools} also provides the extensible harpoons shown above. They’re taken from \cite{6}. For those liking visuals, here are the macros in use in the order listed in the two boxes
3.3.2 Braces and brackets

\[ \text{\LaTeX} \] defines other kinds of extensible symbols like \texttt{\overbrace} and \texttt{\underbrace}, but sometimes you may want another symbol, say, a bracket.

\begin{align*}
\underbracket*[3pt]{xxx \ yyy}_{zzz} & \quad \text{and} \quad \underbracket*[1pt]{xxx \ yyy}_{zzz} \\
\overbracket*[3pt]{xxx \ yyy} & \quad \text{and} \quad \overbracket*[1pt]{xxx \ yyy}
\end{align*}

The commands \texttt{\underbracket} and \texttt{\overbracket} are inspired by [6], although the implementation here is slightly different. Used without the optional arguments the bracket commands produce this:

\begin{align*}
\underbracket{foo \ bar}_{baz} & \quad \text{and} \quad \underbracket[3pt]{foo \ bar}_{baz} \\
\overbracket{foo \ bar}^{baz} & \quad \text{and} \quad \overbracket[3pt]{foo \ bar}^{baz}
\end{align*}

The default rule thickness is equal to that of \texttt{\underbrace} (app. 5/18 ex) while the default bracket height is equal to app. 0.7 ex. These values give really pleasing results in all font sizes, but feel free to use the optional arguments. That way you may get “beauties” like

\begin{align*}
\underbracket[3pt]{xxx \ yyy}_{zzz} & \quad \text{and} \quad \underbracket[7pt]{xxx \ yyy}_{zzz} \\
\overbracket[3pt]{xxx \ yyy} & \quad \text{and} \quad \overbracket[7pt]{xxx \ yyy}
\end{align*}
The standard implementation of the math operators \underbrace and \overbrace in \LaTeX has some deficiencies. For example, all lengths used internally are fixed and optimized for 10 pt typesetting. As a direct consequence thereof, using font sizes other than 10 will produce less than optimal results. Another unfortunate feature is the size of the braces. In the example below, notice how the math operator \sum places its limit compared to \underbrace.

\[
\sum_n \underbrace{f o o f}_{zzz}
\]

The blue lines indicate the dimensions of the math operator and the green lines the dimensions of \textit{foo f}. As you can see, there seems to be too much space between the brace and the \textit{zzz} whereas the space between brace and \textit{foo f} is okay. Let's see what happens when we use a bigger font size:

\[
\sum_n \underbrace{f o o f}_{ZZZ}
\]

Now there's too little space between the brace and the \textit{zzz} and also too little space between the brace and the \textit{foo f}. If you use Computer Modern you'll actually see that the \textit{f} overlaps with the brace! Let's try in \footnotesize:

\[
\sum_n \underbrace{f o o f}_{zzz}
\]

Here the spacing above and below the brace is quite excessive.

As \overbrace has the exact same problems, there are good reasons for \texttt{mathtools} to make redefinitions of \underbrace and \overbrace. These new versions work equally well in all font sizes and fixes the spacing issues and apart from working with the default Computer Modern fonts, they also work with the packages mathpazo, pmath, fourier, eulervm, cmbright, and mathptmx. If you use the ccfonts to get the full Concrete fonts, the original version saved under the names \LaTeXunderbrace and \LaTeXoverbrace are better, due to of the special design of the Concrete extensible braces. In that case you should probably just add the lines

\[
\let\underbrace\LaTeXunderbrace\n\let\overbrace\LaTeXoverbrace
\]

to your preamble after loading \texttt{mathtools} which will restore the original definitions of \overbrace and \underbrace.

3.4 New mathematical building blocks

In this part of the manual, various mathematical environments are described.
3.4.1 Matrices

All of the amsmath matrix environments center the columns by default, which is not always what you want. Thus mathtools provides a starred version for each of the original environments. These starred environments take an optional argument specifying the alignment of the columns, so that

\[
\begin{pmatrix*}[r] 
-1 & 3 \\
2 & -4 
\end{pmatrix*}
\]

yields

\[
\begin{pmatrix}
-1 & 3 \\
2 & -4
\end{pmatrix}
\]

The optional argument (default is [c]) can be any column type valid in the usual array environment.

While we are at it, we also provide fenced versions of the smallmatrix environment. To keep up with the naming of the large matrix environments, we provide both a starred and a non-starred version. Since smallmatrix is defined in a different manner than the matrix environment, the option to say smallmatrix* has to be either c, l or r. The default is c, which can be changed globally using the smallmatrix-align=⟨c,l or r⟩.

\[
\begin{smallmatrix*}[c] 
0 & 0 \\
0 & 0
\end{smallmatrix*}
\]

The optional argument (default is [c]) can be any column type valid in the usual array environment.
\[
\begin{bsmallmatrix}
a & -b \\
- c & d
\end{bsmallmatrix}
\begin{bsmallmatrix*}[r]
a & -b \\
- c & d
\end{bsmallmatrix*}
\]
yields
\[
\begin{bmatrix}
a - b \\
- c & d
\end{bmatrix}
\begin{bmatrix}
a - b \\
- c & d
\end{bmatrix}
\]
Inside the Xsmallmatrix construction a small space is inserted between the fences and the contents, the size of it can be changed using \texttt{smallmatrix-align=\langle some spacing command\rangle}, the default is \texttt{,}. As an extra trick the fences will behave as open and closing fences in constrast to their auto-scaling nature.\textsuperscript{6}

\subsection*{3.4.2 The multlined environment}

\[
\begin{multlined}[t]\framebox[4cm]{first} \\
\framebox[4cm]{last}
\end{multlined} B
\]

Some of the amsmath environments exist in two forms: an outer and an inner environment. One example is the pair \texttt{gather} & \texttt{gathered}. There is one important omission on this list however, as there is no inner \texttt{multlined} environment, so this is where mathtools steps in.

One might wonder what the sensible behavior should be. We want it to be an inner environment so that it is not wider than necessary, but on the other hand we would like to be able to control the width. The current implementation of \texttt{multlined} handles both cases. The idea is this: Set the first line flush left and add a hard space after it; this space is governed by the \texttt{firstline-afterskip} key. The last line should be set flush right and preceded by a hard space of size \texttt{lastline-preskip}. Both these hard spaces have a default value of \texttt{\multlinegap}. Here we use a ‘t’ in the first optional argument denoting a top-aligned building block (the default is ‘c’).

\[
A = \begin{multlined}[t]
\framebox[4cm]{first} \\
\framebox[4cm]{last}
\end{multlined} B
\]
\textsuperscript{6}\texttt{left} and \texttt{right} creates an \texttt{inner} construction, and not as one might expect something where a preceding \texttt{\sin} sees an opening fence, thus the space before or after may be too large. Inside this construction they behave.
Note also that \texttt{multlined} gives you access to an extended syntax for \texttt{\shoveleft} and \texttt{\shoveright} as shown in the example below.

\[
\begin{multlined}
\framebox[.65\textwidth]{First line} \hspace{0.8cm} \ \ \\
\framebox[.5\textwidth]{Second line} \hspace{0.8cm} \ \ \\
\shoveleft{L+E+F+T} \hspace{0.8cm} \ \ \\
\shoveright{R+I+G+H+T} \hspace{0.8cm} \ \ \\
\shoveleft[1\text{cm}]{L+E+F+T} \hspace{0.8cm} \ \ \\
\shoveright[\widthof{$R+I+G+H+T$}]{R+I+G+H+T} \hspace{0.8cm} \ \ \\
\framebox[.65\textwidth]{Last line}
\end{multlined}
\]

First line

Second line  

\[L+E+F+T\]  

\[R+I+G+H+T\]  

\[L+E+F+T\]  

\[R+I+G+H+T\]  

Last line

You can also choose the width yourself by specifying it as an optional argument:

\[
\begin{multlined}[b][7\text{cm}]
\framebox[4\textwidth]{first} \hspace{0.8cm} \ \ \\
\framebox[4\textwidth]{last}
\end{multlined} = B
\]

\[
\begin{array}{c}
\text{first} \\
\text{last} \quad = B
\end{array}
\]

There can be two optional arguments (position and width) and they’re interchangeable.

**Bug 1:** If used inside an array or a derivative (say, a matrix variant), \texttt{multlined} does not work as expected. The implementation contains an ‘invisible’ line after the first multline row, inside an array this line is no longer ‘invisible’ because array sets \texttt{\baselineskip} to zero. Currently we have no general workaround for this.

**Bug 2:** Due to the way \texttt{multlined} is implemented, certain constructions does not work inside \texttt{multlined}. We have added a hook (\texttt{\MultlinedHook}) that can be added to. The default value is a fix for subarray and crampedsubarray and thus for \texttt{\substack} and \texttt{\crampedsubstack} (and a few others, thus add to the hook, don’t replace it).
This can actually be used to fix Bug 1:

```latex
\usepackage{mathtools,etoolbox}
\newlength\Normalbaselineskip
\setlength\Normalbaselineskip{\baselineskip}
\appto\MultlinedHook{
  \setlength\baselineskip{\Normalbaselineskip}
}
```

Caveat: \shoveleft and \shoveright does not work as expected if used as the last line in multlined.

### 3.4.3 More \texttt{cases}-like environments

| \begin{dcases} & \end{dcases}   | \begin{dcases*} & \end{dcases*} |
| \begin{cases} & \end{cases}    | \begin{cases*} & \end{cases*} |
| \begin{rcases} & \end{rcases}  | \begin{rcases*} & \end{rcases*} |
| \begin{drcases} & \end{drcases} | \begin{drcases*} & \end{drcases*} |
| \begin{cases*} & \end{cases*} |

Anyone who have tried to use an integral in the regular \texttt{cases} environment from \texttt{amsmath} will have noticed that it is set as

\[
\begin{cases}
E = mc^2 & \text{Nothing to see here} \\
\int x-3 \, dx & \text{Integral is text style}
\end{cases}
\]

\[
\begin{cases*}
E = mc^2 & c \approx 3.00 \times 10^8 \, \text{m/s} \\
\int x-3 \, dx & \text{Integral is display style}
\end{cases*}
\]

\[
\begin{cases}
E = mc^2 & c \approx 3.00 \times 10^8 \, \text{m/s} \\
\int x-3 \, dx & \text{Integral is display style}
\end{cases}
\]

Additionally the environment \texttt{dcases*} acts just the same, but the second column is set in the normal roman font of the document.\(^7\)

\[
\begin{dcases*}
\begin{cases*}
\end{dcases*}
\end{dcases*}
\]

\[^7\text{Or rather: it inherits the font characteristics active just before the \texttt{dcases*} environment.}\]
E = m c^2 & Nothing to see here \[ \
\int x-3\, dx & Integral is display style
\end{dcases*}
\]

\[
\]

a = \begin{dcases*}
E = mc^2 & Nothing to see here
\int x - 3\, dx & Integral is display style
\end{dcases*}

The environments `rcases`, `rcases*`, `drcases` and `drcases*` are equivalent to `cases` and `dcases`, but here the brace is placed on the right instead of the left.

\[
\begin{rcases*}
x^2 & for $x>0$\]
x^3 & else
\end{rcases*} \quad \Rightarrow \cdots
\]

3.4.4 Emulating indented lines in alignments

In [7], Ellen Swanson recommends that when ever one has a long displayed formula, spanning several lines, and it is unfeasible to align against a relation within the first line, then all lines in the display should be aligned at the left most edge of the first line, and all subsequent lines should be indented by 2 em (or if needed by a smaller amount). That is we are talking about displays that end up looking like this:

```
\MoveEqLeft\framebox[10cm][c]{Long first line}
\coloneqq \framebox[6cm][c]{\phantom{g} 2nd line}
\leq \ldots
```

Traditionally one could do this by starting subsequent lines by `& \quad ...`, but that is tedious. Instead the example above was made using `\MoveEqLeft`:

```
\begin{align*}
\MoveEqLeft \framebox[10cm][c]{Long first line}\\
&= \framebox[6cm][c]{\phantom{g} 2nd line}\\
&\leq \ldots
\end{align*}
```

`\MoveEqLeft` is placed instead of the `&` on the first line, and will effectively move the entire first line `[\langle number\rangle]` of ems to the left (default is 2). If you choose to align to the
right of the relation, use \texttt{MoveEqLeft[3]} to accommodate the extra distance to the alignment point:

\begin{align*}
\texttt{MoveEqLeft[3]} \framebox[10cm][c]{Part 1}
= {} & \framebox[8cm][c]{2nd line} \\
& + \framebox[4cm][c]{ last part}
\end{align*}

3.4.5 Boxing a single line in an alignment

The amsmath package provie the \texttt{boxed} macro to box material in math mode. But this of course will not work if the box should cross an alignment point. We provide a macro that can.\footnote{Evolved from a request by Merciadri Luca 2010/06/28 on comp.text.tex Reimplemented by Florent Chervet (GL) 2011/06/11 on comp.text.tex}

\begin{align*}
\texttt{Aboxed}{\langle \text{left hand side} \quad \& \quad \text{right hand side}\rangle}
\end{align*}

Example

\begin{align*}
\begin{align*}
\texttt{Aboxed}{ f(x) \quad & = \quad \int h(x) \, dx} \\
& = g(x)
\end{align*}
\end{align*}

Resulting in:

\[ f(x) = \int h(x) \, dx \\
= g(x) \]

One can have multiple boxes on each line, and the »& right hand side« can even be missing. Here is an example of how the padding in the box can be changed

\begin{align*}
\begin{align*}
\texttt{setlength\fboxsep{1em}}
\texttt{Aboxed}{ f(x) \quad & = \quad 0} \\
& \quad \texttt{Aboxed}{ g(x) \quad & = \quad b} \\
\texttt{Aboxed}{ h(x)} \\
\texttt{Aboxed}{ i(x)}
\end{align*}
\end{align*}

\[ f(x) = 0 \\
g(x) = b \\
h(x) \\
i(x) \]
Note how the `\fboxsep` change only affect the box coming immediately after it.

As `\Aboxed` looks for the alignment `&` it may be necessary to *hide* constructions like matrices that also make use of `&. Just add a set of braces around the construction you want to hide.

### 3.4.6 Adding arrows between lines in an alignment

This first macro is a bit misleading, it is only intended to be used in combination with the `alignat(*)` environment.

```
\ArrowBetweenLines[(symbol)]
\ArrowBetweenLines*[(symbol)]
```

To add, say ↓ between two lines in an alignment use `\ArrowBetweenLines` and the `alignat` environment (note the extra pair of `&` in front):

```
\begin{alignat}{2}
  && \framebox[1.5cm]{} &= \framebox[3cm]{} \\
  \ArrowBetweenLines \% \Updownarrow is the default
  && \framebox[1.5cm]{} &= \framebox[2cm]{} \\
\end{alignat}
```

resulting in

```
\begin{alignat}{2}
  && \framebox[1.5cm]{} &= \framebox[3cm]{} \\
  \ArrowBetweenLines\%\Updownarrow is the default
  && \framebox[1.5cm]{} &= \framebox[2cm]{} \\
\end{alignat}
```

resulting in

```
\begin{alignat}{2}
  && \framebox[1.5cm]{} &= \framebox[3cm]{} \\
  \ArrowBetweenLines\%\Updownarrow is the default
  && \framebox[1.5cm]{} &= \framebox[2cm]{} \\
\end{alignat}
```

resulting in

```
\begin{alignat}{2}
  && \framebox[1.5cm]{} &= \framebox[3cm]{} \\
  \ArrowBetweenLines\%\Updownarrow is the default
  && \framebox[1.5cm]{} &= \framebox[2cm]{} \\
\end{alignat}
```

Note the use of `&&` starting each regular line of math. For adding the arrow on the right, use `\ArrowBetweenLines*[(symbol)]`, and end each line of math with `&&`.

```
\begin{alignat*}{2}
  \&\framebox[1.5cm]{} \&\framebox[3cm]{} \&\framebox[2cm]{} \&\\\
  \ArrowBetweenLines*[\Downarrow]
\end{alignat*}
```

resulting in

```
\begin{alignat*}{2}
  \&\framebox[1.5cm]{} \&\framebox[3cm]{} \&\framebox[2cm]{} \&\\\
  \ArrowBetweenLines*[\Downarrow]
\end{alignat*}
```

resulting in

```
\begin{alignat*}{2}
  \&\framebox[1.5cm]{} \&\framebox[3cm]{} \&\framebox[2cm]{} \&\\\
  \ArrowBetweenLines*[\Downarrow]
\end{alignat*}
```

### 3.4.7 Centered `\vdots`

If one want to mark a vertical continuation, there is the `\vdots` command, but combine this with an alignment and we get something rather suboptimal

\footnote{Note that internally `\Aboxed` does use `boxed`.}
It would be nice to have (1) a \texttt{\vdots} centered within the width of another symbol, and (2) a construction similar to \texttt{\ArrowBetweenLines} that does not take up so much space. We provide both.

\begin{align*}
a &= b \\
& \vdots \\
& = c \\
& \shortvdotswithin{=} \\
& = d
\end{align*}

yielding

\[
\begin{array}{c}
a = b \\
\vdots \\
= c \\
\vdots \\
= d
\end{array}
\]

Thus \texttt{\vdotswithin{}} create a box corresponding to {}= and typeset a »:« centered inside it. When doing this as a normal line in an alignment leaves us with excessive space which \texttt{\shortvdotswithin{}} takes care with for us.

\texttt{\shortvdotswithin{}} corresponds to

\begin{verbatim}
\MTFlushSpaceAbove
& \vdotswithin{=} \\
& \vdotswithin{=} \\
\MTFlushSpaceBelow
\end{verbatim}

whereas \texttt{\shortvdotswithin*{}} is the case with \texttt{\vdotswithin{}} \& \texttt{\vdots}. This also means one cannot write more on the line when using \texttt{\shortvdotswithin} or the starred version. But one can de-construct the macro and arrive at
\begin{alignat*}{3}
A &+ B &&= C &&+ D \\
\&\vdotswithin{+} &&&& \vdotswithin{+} \\
C &+ D &&= Y &&+K
\end{alignat*}

yielding

\begin{align}
A + B &= C + D \\
C + D &= Y + K
\end{align}

If one has the need for such a construction.

The de-spaced version does support the \texttt{spreadlines} environment. The actual amount of space being \texttt{flushed} above and below can be controlled by the user using the two options indicated. Their original values are \texttt{2.15\origjot} and \texttt{\origjot} respectively (\texttt{\origjot} is usually 3pt).

\subsection{Intertext and short intertext}

\texttt{amsmath} provides the command \texttt{\intertext} for interrupting a multiline display while still maintaining the alignment points. However the spacing often seems quite excessive as seen below.

\begin{align}
\begin{align}
\intertext{Some text}
\end{align}
\end{align}

\begin{align}
\begin{align}
\intertext{Some text}
\end{align}
\end{align}

\begin{align}
\begin{align}
\intertext{Some text}
\end{align}
\end{align}

Using the command \texttt{\shortintertext} alleviates this situation somewhat:

\begin{align}
\begin{align}
\shortintertext{Some text}
\end{align}
\end{align}

\begin{align}
\begin{align}
\shortintertext{Some text}
\end{align}
\end{align}

\begin{align}
\begin{align}
\shortintertext{Some text}
\end{align}
\end{align}
\[ a = b \quad (11) \]

Some text

\[ c = d \quad (12) \]

It turns out that both \texttt{\shortintertext} and the original \texttt{\intertext} from amsmath has a slight problem. If we use the \texttt{spreadlines} (see section 4.4) to open up the equations in a multiline calculation, then this opening up value also applies to the spacing above and below the original \texttt{\shortintertext} and \texttt{\intertext}. It can be illustrated using the following example, an interested reader, can apply it with and without the original \texttt{\intertext} and \texttt{\shortintertext}.

\begin{verbatim}
\% the original \intertext and \shortintertext
\mathtoolsset{original-intertext,original-shortintertext}
\newcommand\myline{\par\noindent\rule{\textwidth}{1mm}}
\myline
\begin{spreadlines}{1em}
\begin{align*}
AA \& BB \\ \intertext{\myline}
AA \& BB \\ \shortintertext{\myline}
AA \& BB
\end{align*}
\end{spreadlines}
\myline
\end{verbatim}

We now fix this internally for both \texttt{\intertext} and \texttt{\shortintertext}, plus we add the possibility to fine tune spacing around these constructions. The original versions can be brought back using the \texttt{original-\textbackslash x} keys below.

\begin{verbatim}
\intertext{\texttt{\langle text\rangle}}
\shortintertext{\texttt{\langle text\rangle}}
original-intertext = true|false \ (default: false)
original-shortintertext = true|false \ (default: false)
above-intertext-sep = \langle dimen\rangle \ (default: 0pt)
below-intertext-sep = \langle dimen\rangle \ (default: 0pt)
above-shortintertext-sep = \langle dimen\rangle \ (default: 3pt)
below-shortintertext-sep = \langle dimen\rangle \ (default: 3pt)
\end{verbatim}

The updated \texttt{\shortintertext} will look like the original version unless for areas with an enlarged \texttt{\jot} value (see for example the \texttt{spreadlines}, section 4.4). Whereas \texttt{\intertext} will have a slightly smaller value above and below (corresponding to about 3pt less space above and below), the spacing around \texttt{\intertext} should now match the normal spacing going into and out of an \texttt{align}.

\textbf{Tip}: \texttt{\intertext} and \texttt{\shortintertext} also works within \texttt{gather}.
3.6 Paired delimiters

\[\text{\textbackslash DeclarePairedDelimiter\{cmd\}\{left\_delim\}\{right\_delim\}}\]

In the amsmath documentation it is shown how to define a few commands for typesetting the absolute value and norm. These definitions are:

\[
\newcommand*\abs[1]{\lvert#1\rvert}
\newcommand*\norm[1]{\lVert#1\rVert}
\]

While they produce correct horizontal spacing you have to be careful about the vertical spacing if the argument is just a little taller than usual as in

\[\left| \frac{a}{b} \right|\]

Here it won’t give a nice result, so you have to manually put in either \texttt{\textbackslash left}–\texttt{\textbackslash right} pair or a \texttt{\textbackslash bigl}–\texttt{\textbackslash bigr} pair. Both methods mean that you have to delete your \texttt{\abs} command, which may not sound like an ideal solution.

With the command \texttt{\textbackslash DeclarePairedDelimiter} you can combine all these features in one easy to use command. Let’s show an example:

\[
\text{\textbackslash DeclarePairedDelimiter}\text{\abs}\{\lvert\}\{\rvert\}
\]

This defines the command \texttt{\abs} just like in the amsmath documentation but with a few additions:

- A starred variant: \texttt{\abs*} produces delimiters that are preceded by \texttt{\textbackslash left} and \texttt{\textbackslash right} resp.:

\[
\left[\right. \quad \texttt{\abs*}\{\texttt{\frac{a}{b}}\} \\
\left] \quad \left| \frac{a}{b} \right|\]

- A variant with an optional argument: \texttt{\abs[\texttt{size\_cmd}]}, where \texttt{\textbackslash size\_cmd} is either \texttt{\textbackslash big}, \texttt{\Big}, \texttt{\bigg}, or \texttt{\Bigg} (if you have any bigggger versions you can use them too).

\[
\left[\right. \quad \texttt{\abs[\texttt{\Bigg}]\{\texttt{\frac{a}{b}}\}} \\
\left] \quad \left| \frac{a}{b} \right|\]
\begin{Verbatim}
\DeclarePairedDelimiterX{\innerp}[2]{\langle}{\rangle}{#1}
\end{Verbatim}

\begin{Verbatim}
\DeclarePairedDelimiterX{\braket}[3]{\langle}{\rangle}{#1\mathopen{}#2\mathopen{}#3}
\end{Verbatim}

\textit{Note the use of «widthopen» in the \textit{code} of \textit{braket}, this is very important when a scalable delimiter is being used and it does not present itself as a left or right delimiter. You will see why it is needed if you use \textit{braket}\{\textit{A}\}\{-\textit{B}\} in a version without \textit{widthopen}.}\end{Verbatim}

Let us do some examples. First we want to prepare a macro for inner products, with two arguments such that we can hide the character separating the arguments (a journal style might require a semi-colon, so we will save a lot of hand editing). This can be done via
\begin{Verbatim}
\DeclarePairedDelimiterX{\innerp}[2]{\langle}{\rangle}{#1,#2}
\end{Verbatim}

More interestingly we can refer to the size inside the \textit{code}. Here we do a weird three argument ‘braket’
\begin{Verbatim}
\DeclarePairedDelimiterX{\braket}[3]{\langle}{\rangle}{#1\delimsize\vert\mathopen{}#2\delimsize\vert\mathopen{}#3}
\end{Verbatim}

Then we get
\begin{Verbatim}
\innerp*{A}{\frac{1}{2}}\quad\braket[\Big]{B}{\sum_{k} f_{k}}{C}
\end{Verbatim}

\begin{align*}
\langle A, \frac{1}{2} \rangle \quad \langle B \mid \sum_{k} C \rangle
\end{align*}

\footnote{Basically, the problem is that \texttt{\textbackslash{}vert} is a ‘symbol’, thus \texttt{| - B} is interpreted \textit{subtraction}, not a symbol followed by negative \textit{B}. When \texttt{\textbackslash{}mathopen{}} is added, \LaTeX{} is told that an opening delimiter just occurred, and it will adjust the minus accordingly.}
With the inner scaling, we can provide macros whose syntax closely follow the mathematical meaning. For building sets, try this\(^\text{10}\)

\begin{verbatim}
% just to make sure it exists
\providecommand\given{}
% can be useful to refer to this outside \Set
\newcommand\SetSymbol[1][]{%
  \nonscript\:#1\vert
  \allowbreak
  \nonscript\:
  \mathopen{}}
\DeclarePairedDelimiterX\Set[1]{\}{%  
  \renewcommand\given{\SetSymbol[\delimsize]}
  #1}
\end{verbatim}

Thus we end up with a syntax much closer to how we read this aloud. Also we hide the ‘given’ symbol for easy replacement.\(^\text{11}\)

Combining with etoolbox it becomes easy to make a function that automatically provide a marker for a blank argument:

```
\usepackage{etoolbox}
\DeclarePairedDelimiterX\norm[1]\lVert\rVert{
  \ifblank{#1}{\cdot}{#1}
}
```

Then \texttt{\norm{}} will give you \(\|·\|\) while \texttt{\norm{a}} gives the expected \(\|a\|\).

\begin{verbatim}
\DeclarePairedDelimiterXPP{〈}{cmd}{〈num args〉}{〈pre code〉}{〈left_delim〉}{〈right_delim〉}{〈post code〉}{〈body〉}
\end{verbatim}

\texttt{\DeclarePairedDelimiterXPP{〈}{cmd}{〈num args〉}{〈pre code〉}{〈left_delim〉}{〈right_delim〉}{〈post code〉}{〈body〉}} has an annoying caveat: it is very hard to make a macro \texttt{\lnorm{a}} that should result in \(\|a\|_2\).\(^\text{12}\)

As a consequence we provide \texttt{\DeclarePairedDelimiterXPP{〈}{cmd}{〈num args〉}{〈pre code〉}{〈left_delim〉}{〈right_delim〉}{〈post code〉}{〈body〉}. With the addition of the \{〈pre code〉\} and \{〈post code〉\} it is identical to \texttt{\DeclarePairedDelimiterXPP{〈}{cmd}{〈num args〉}{〈pre code〉}{〈left_delim〉}{〈right_delim〉}{〈post code〉}{〈body〉}. It should be interpreted as

\(^{10}\)The reason for using a separate \texttt{\SetSymbol} macro has to do with complicated set definitions, where the condition spans several lines. In this case \texttt{\Set} cannot be used. Thus it is nice to be able to refer to the specific set building symbol we have decided to use in this document. Also remember to add \texttt{\allowbreak} before the proceeding inserted space. Then that space will disappear when a line break occurs.

\(^{11}\)The \texttt{\nonscript} construction removes the \texttt{:} in sub- and superscript, this might not always be preferable. You can use \texttt{\mathchoice{\cdot}{\cdot}{\,}{\,}} instead of \texttt{\nonscript\:}.

\(^{12}\)The added \texttt{\_2} is hard to get around the argument parsing.

\(^{13}\)Extended \texttt{\DeclarePairedDelimiterXPP{〈}{cmd}{〈num args〉}{〈pre code〉}{〈left_delim〉}{〈right_delim〉}{〈post code〉}{〈body〉}.
An $L^2$ norm can now be defined as
\[
\DeclarePairedDelimiterXPP{lnorm}[1]{\lVert}{\rVert}_{2}{#1}
\]

A probability macro with build in support for conditionals (\texttt{\textbackslash given} initialized as above)
\[
\DeclarePairedDelimiterXPP{Prob}[1]{\mathbb{P}}(){}{
  \renewcommand\given{\nonscript\:\delimsize\vert\nonscript\:\mathopen{}}
  #1}
\]

Thus giving support for \texttt{\textbackslash Prob\{A \textbackslash given \ B\}}.

\textbf{Note 1: } As the number of arguments increase the \texttt{\DeclarePairedDelimiter...} macros become hard for users to understand. A key-value interface would be better. This is planed for a future release. In [link](http://tex.stackexchange.com/a/136767/3929) there is a suggested replacement for \texttt{\DeclarePairedDelimiter}, that greatly reduces the number of macros and provides a key-val interface. However, the code use \texttt{xparse}, and if we want to use \texttt{xparse} for some of our macros, we might just as well rewrite the entire mathtools package in expl3. Also it is not obvious how to get \texttt{xparse} to support \texttt{[3]} for the number of arguments. We will consider this for a future release.

\textbf{Note 2: } If you want to define your own manual scaler macros, it is importent that you besides \texttt{\textbackslash foo} also defines \texttt{\fool} and \texttt{\foor}. When a scaler is specified, in say \texttt{\abs\{big\}(arg)}, we actually use \texttt{\bigl and \bigr}.

\subsection{Expert use}

Within the starred version of \texttt{\DeclarePairedDelimiter} and \texttt{\DeclarePairedDelimiterX} we make a few changes such that the auto scaled \texttt{\left} and \texttt{\right} fences behave as opening and closing fences, i.e. sin\texttt{(x)} vs. sin\texttt{(x)} (the later made via $\sin\left(x\right)$), notice the gab between ‘sin’ and ‘(’. In some special cases it may be useful to be able to tinker with the behavior.

\begin{verbatim}
\reDeclarePairedDelimiterInnerWrapper{\abs}{star}{#1#2#3}
\reDeclarePairedDelimiterInnerWrapper{\abs}{nostarnonscaled}{\mathinner{#1#2#3}}
\reDeclarePairedDelimiterInnerWrapper{\abs}{nostarscaled}{\mathinner{#1#2#3}}
\end{verbatim}

Internally several macros are created, including three call backs that take care of the formatting. There is one internal macro for the starred version, labeled star, the other two are labeled nostarnonscaled and nostarscaled. Within \texttt{(code)}, #1 will be replaced by the (scaled) left fence, #3 the corresponding (scaled) right fence, and #2 the stuff in between. For example, here is how one might turn the content into \texttt{\mathinner{}}:

\begin{verbatim}
\DeclarePairedDelimiter\abs{\lvert}{\rvert}
\reDeclarePairedDelimiterInnerWrapper{\abs}{star}{#1#2#3}
\reDeclarePairedDelimiterInnerWrapper{\abs}{nostarnonscaled}{\mathinner{#1#2#3}}
\reDeclarePairedDelimiterInnerWrapper{\abs}{nostarscaled}{\mathinner{#1#2#3}}
\end{verbatim}
The default values for the call backs corresponds to

- **star:** \mathopen{} \mathclose{} \aftergroup \egroup \mathopen{} \mathclose{} \aftergroup \egroup \mathopen{} \mathclose{} \aftergroup \egroup
- **nostarnonscaled:** \mathopen{} \mathclose{} \mathopen{} \mathclose{}
- **nostarscaled:** \mathopen{} \mathclose{} \mathopen{} \mathclose{}

The two nostar... versions look the same, but they are not. In most (math) fonts, the first item in this list will be different from the rest (the superscript sits higher).\(^{14}\)

\mathclose{} \vert^2 \mathclose{} \vert^2 \mathclose{} \vert^2

**Breaking change:** Prior to May 2017, we used two wrappers, the other named nostar. As of May 2017 nostar has been split into nostarnonscaled and nostarscaled and nostar alone is no longer supported (will give an error).

**Note:** Since we are using macros to add the \left...\right constructions around some body, it is (in principle) possible to make such a construction breakable across lines, even breakable within an align construction. Currently, this can only be applied to macros made using \DeclarePairedDelimiter and *not* macros made using \DeclarePairedDelimiterX or \DeclarePairedDelimiterXPP as the contents is typeset inside a group (to limit \delimsize) and thus hide any \& or \\\ from align and align breaks down.

When \DeclarePairedDelimiter is used, Sebastien Gouezel has provided the following example

\newcommand\MTkillspecial[1]{{% helper macro \begingroup \catcode\&=9 \let\\relax % \scantokens{#1} % \egroup }
\DeclarePairedDelimiter\abs\lvert\rvert
\ReDeclarePairedDelimiterInnerWrapper\abs{star}{\mathopen{#1\vphantom{\MTkillspecial{#2}}\kern-\nulldelimiterspace}\right.}{#2
\mathclose{\left.\kern-\nulldelimiterspace\vphantom{\MTkillspecial{#2}}#3}}

Then this example works just fine:

\begin{align*}
f(a) &= \begin{aligned}[t]
\abs*{ & \frac{1}{2}+\cdots
& \frac{1}{2}+\cdots }
\end{aligned}
\end{align*}

\(^{14}\)Interestingly it did not show up in the font of this manual, which uses the fourier font set.
\[ f(a) = \frac{1}{2} + \cdots + \frac{1}{2} \]

### 3.7 Special symbols

This part of the manual is about special symbols. So far only one technique is covered, but more will come.

#### 3.7.1 Left and right parentheses

\[ \text{	exttt{\textbackslash lparen \textbackslash rparen}} \]

When you want a big parenthesis or bracket in a math display you usually just type

\[ \texttt{\left( ... \right)} \text{ or } \texttt{\left[ ... \right]} \]

\LaTeX{} also defines the macro names \texttt{\textbackslash lbrack} and \texttt{\textbackslash rbrack} to be shorthands for the left and right square bracket resp., but doesn’t provide similar definitions for the parentheses. Some packages need command names to work with\footnote{The \texttt{empheq} package needs command names for delimiters in order to make auto-scaling versions.} so \texttt{mathtools} defines the commands \texttt{\textbackslash lparen} and \texttt{\textbackslash rparen} to represent the left and right parenthesis resp.

#### 3.7.2 Vertically centered colon

\[ \text{	exttt{\textbackslash vcentcolon \texttt{\textbackslash ordinarycolon}}} \]

When trying to show assignment operations as in \( a := b \), one quickly notices that the colon is not centered on the math axis as the equal sign, leading to an odd-looking output. The command \texttt{\textbackslash vcentcolon} is a shorthand for such a vertically centered colon, and can be used as in $a \vcentcolon= b$ and results in the desired output: \( a := b \), for now.

Typing \texttt{\textbackslash vcentcolon} every time is quite tedious, so one can use the key \texttt{centercolon} to make the colon active instead.

\begin{verbatim}
\mathtoolsset{centercolon}
[ \]
  a := b
\]
\mathtoolsset{centercolon=false}
\end{verbatim}

In this case the command \texttt{\textbackslash ordinarycolon} typesets an \ldots ordinary colon (what a surprise).
Warning: centercolon does not work with languages that make use of an active colon, most notably French. Sadly the babel package does not distinguish between text and math when it comes to active characters. Nor does it provide any hooks to deal with math. So currently no general solution exists for this problem.

\coloneqq \Coloneqq \coloneq \Coloneq
\eqqcolon \Eqqcolon \eqcolon \Eqcolon
\colonapprox \Colonapprox \colonsim \Colonsim
\dblcolon

The font packages txfonts and pxfonts provides various symbols that include a vertically centered colon but with tighter spacing. For example, the combination := exists as the symbol \coloneqq which typesets as := instead of :=. The primary disadvantage of using these fonts are the support packages’ lack of support for amsmath (and thus mathtools) and worse yet, the side-bearings are way too tight; see [4] for examples. If you’re not using these fonts, mathtools provides the symbols for you. Here are a few examples:

\[
\begin{align*}
a \coloneqq b & \quad c \Colonapprox d & \quad e \dblcolon f \\
\end{align*}
\]

a := b  c ≈ d  e :: f

3.7.3 A few missing symbols

Most provided math font sets are missing the symbols \nuparrow and \ndownarrow (i.e. negated up- and downarrow) plus a ‘big’ version of \times. Therefore we will provide constructed versions of these whenever they are not already available.

\nuparrow
\ndownarrow
\bigtimes

Note: that these symbols are constructed via features from the graphicx package, and thus may not display correctly in most DVI previewers. Also note that \nuparrow and \ndownarrow are constructed via \ngrightarrow and \nleftarrow respectively, so these needs to be present. Usually this is done via amssymb, but some packages may be incompatible with amssymb so the user will have to load amssymb or a similar package, that provides \ngrightarrow and \nleftarrow, themselves.

With those requirements in place, we have

\[
\lim_{a \ndownarrow 0} f(a) \neq \bigtimes_n X_n \quad \frac{\bigtimes_{k=1}^7 B_k \nuparrow \Omega}{2}
\]

\[\lim_{a \to 0} f(a) \neq \bigtimes_n X_n \quad \frac{\sum_{k=1}^n B_k \nuparrow \Omega}{2}\]
4 A tribute to Michael J. Downes

Michael J. Downes (1958–2003) was one of the major architects behind amsmath and member of the \LaTeX Team. He made many great contributions to the \LaTeX community; not only by the means of widely spread macro packages such as amsmath but also in the form of actively giving advice on newsgroups. Some of Michael's macro solutions on the newsgroups never made it into publicly available macro packages although they certainly deserved it, so mathtools tries to rectify this matter. The macros described in this section are either straight copies or heavily inspired by his original postings.

4.1 Mathematics within italic text

\begin{quote}\itshape
Compare these lines: \par
\mathtoolsset{mathic} % or \mathtoolsset{mathic=true}
Subset of \textstyle \setminus(V) and subset of \textstyle \setminus(A). \par
\mathtoolsset{mathic=false}
Subset of \textstyle \setminus(V) and subset of \textstyle \setminus(A).
\par
\end{quote}

Compare these lines:
Subset of \textstyle \setminus(V) and subset of \textstyle \setminus(A).

As of 2013, \textstyle \setminus are robust, as is the italic corrected versions.

Caveat: Italic correction is a treacherous area. For example any penalties will cancel the italic correction inserted by \textstyle \setminus (for an explanation see [8], section 4.3.3). We have changed Michaels original to accomodate one specific penalty construction: the \texttt{tie}, i.e., »text\textstyle \setminus « will work as expected (as of July, 2014).

4.2 Left sub/superscripts

\begin{quote}\prescript{\text{sup}}{\text{sub}}{\text{arg}}\prescript-sup-format = \langle cmd \rangle \prescript-sub-format = \langle cmd \rangle \prescript-arg-format = \langle cmd \rangle \end{quote}

Sometimes one wants to put a sub- or superscript on the left of the argument. The \texttt{\prescript} command does just that:
The formatting of the arguments is controlled by three keys. This silly example shows you how to use them:

\newcommand*{\myisotope}[3]{%\begin{group} % to keep changes local. We cannot use a brace group
% as it affects spacing!
\mathtoolsset{
    prescript-sup-format=\mathit,
    prescript-sub-format=\mathbf,
    prescript-arg-format=\mathrm,
}\prescript{#1}{#2}{#3} %
\end{group} }
\[\myisotope{A}{Z}{X} \to \myisotope{A-4}{Z-2}{Y} + \myisotope{4}{2}{\alpha}\]

(Though a package like \texttt{mhchem} might be more suitable for this type of material.)

\section{4.3 Declaring math sizes}

\DeclareMathSizes{(dimen)}{(dimen)}{(dimen)}{(dimen)}

If you don't know about \texttt{\DeclareMathSizes}, then skip the rest of this text. If you do know, then all that is needed to say is that with mathtools it is patched so that all regular dimension suffixes are now valid in the last three arguments. Thus a declaration such as

\DeclareMathSize{9.5dd}{9.5dd}{7.5dd}{6.5dd}

will now work (it doesn't in standard \texttt{\LaTeX}). When this bug has been fixed in \texttt{\LaTeX}, this fix will be removed from mathtools.

The fix was added to the \texttt{\LaTeX} kernel i 2015. We will continue to provide it on older kernels.
4.4 Spreading equations

\begin{spreadlines}{20pt}
Large spaces between the lines.
\begin{gather}
 a=b \\
 c=d
\end{gather}
\end{spreadlines}
Back to normal spacing.
\begin{gather}
 a=b \\
 c=d
\end{gather}

Large spaces between the lines.

\begin{equation}
 a = b \quad (13)
\end{equation}
\begin{equation}
 c = d \quad (14)
\end{equation}
Back to normal spacing.
\begin{equation}
 a = b \quad (15)
\end{equation}
\begin{equation}
 c = d \quad (16)
\end{equation}

4.5 Gathered environments

\begin{lgathered}
\begin{equation}
x=1,\quad x+1=2 \\
y=2
\end{equation}
\end{lgathered}
In a document set in fleqn, you might sometimes want an inner gathered environment that doesn't center its lines but puts them flush left. The \texttt{lgathered} environment works just like the standard \texttt{gathered} except that it flushes its contents left:
Similarly the \texttt{rgathered} puts its contents flush right.

More interesting is probably the command \texttt{newgathered}. In this example we define a gathered version that centers the lines and also prints a star and a number at the left of each line.

\begin{verbatim}
\newcounter{steplinecnt}
\newcommand\stepline{
  \stepcounter{steplinecnt}
  \thesteplinecnt}
\newcommand\steplinecnt{0}
\newcommand\stargathered[
  \llap{\stepline}$*$
  \quad\hfil
  \hfil
  \setcounter{steplinecnt}{0}]
\begin{gather}
\begin{stargathered}
  x=1, \quad x+1=2 \\
  y=2
\end{stargathered}
\end{gather}
\end{verbatim}

With these definitions we can get something like this:

\begin{verbatim}
\begin{gather}
\begin{stargathered}
  x=1, \quad x+1=2 \\
  y=2
\end{stargathered}
\end{gather}
\end{verbatim}

\begin{equation}
\begin{array}{c}
1* \quad x = 1, \quad x + 1 = 2 \\
2* \quad y = 2
\end{array}
\end{equation}

\texttt{renewgathered} renews a gathered environment of course.

In all fairness it should be stated that the original concept by Michael has been extended quite a bit in mathtools. Only the end product of \texttt{lgathered} is the same.

### 4.6 Split fractions

\begin{verbatim}
\splitfrac{(numer)}{(denom)} \splitdfrac{(numer)}{(denom)}
\end{verbatim}

These commands provide split fractions e.g., multiline fractions:

\begin{verbatim}
\[
\begin{array}{c}
  a = \frac{
    \begin{split}
      & xy + xy + xy + xy + xy \\
      & (+ xy + xy + xy + xy)
    \end{split}
  }{z}
\end{array}
\end{verbatim}

\[
\begin{array}{c}
  \begin{split}
    & xy + xy + xy + xy
  \end{split}
\end{array}
\end{verbatim}

36
\[
\begin{align*}
a &= \frac{\xy + \xy + \xy + \xy + \xy}{\z} = \frac{\xy + \xy + \xy + \xy + \xy}{\z}
\end{align*}
\]
